

Package ‘rpymat’

April 4, 2023

Type Package

Title Easy to Configure an Isolated 'Python' Environment

Version 0.1.5

Description Aims to create a single isolated 'Miniconda' and 'Python' environment for reproducible pipeline scripts. The package provides utilities to run system command within the 'conda' environment, making it easy to install, launch, manage, and stop 'Jupyter-lab'.

choose-file	2
conda-env	3
jupyter	6
repl_python	8

reticulate-reexports	9
run_command	11
run_script	13

Index	14
--------------	-----------

choose-file	<i>Choose file or directory to open via 'Python'</i>
-------------	--

Description

Choose a directory, one or multiple files to open, or choose a file to save.

Usage

```
choose_fileopen(
  initialfile = NULL,
  multiple = FALSE,
  title = ifelse(multiple, "Choose Files", "Choose a File"),
  message = "",
  verbose = FALSE,
  force = FALSE
)
```

```
choose_filesave()
```

```
choose_directory(
  initialdir = NULL,
  title = "Choose a Directory",
  message = "",
  verbose = FALSE
)
```

Arguments

initialfile, initialdir	initial selection of file or directory
multiple	whether to open multiple files
title, message	dialogue title and message
verbose	whether to verbose debug information
force	whether to force using 'Python' when native R functions are available, default is false

Details

Base-R has `file.choose` function to choose files. However, users cannot select multiple files nor directories. These functions fill the gap by using 'Python' 'tkinter' package. Please make sure that one-time setup function `configure_conda` has executed before running these functions.

The functions must run as interactive mode. If you run the functions on a server, most likely you will get nothing. The functions themselves do not check if you are running under interactive sessions. You must check by yourself.

Value

User-selected paths. If the users select nothing, then NULL will be returned. For multiple file selection, multiple paths will be returned.

Examples

```
if(interactive()) {  
  choose_fileopen(multiple = TRUE)  
}
```

conda-env	<i>'Miniconda' environment</i>
-----------	--------------------------------

Description

These functions/variables are used to configure 'Miniconda' environment.

Usage

```
CONDAENV_NAME(env_name)  
  
conda_path()  
  
conda_bin()  
  
env_path()  
  
list_pkgs(...)  
  
configure_matlab(matlab, python_ver = "auto")  
  
configure_conda(  
  python_ver = "auto",  
  packages = NULL,
```

```

    matlab = NULL,
    update = FALSE,
    force = FALSE
)

remove_conda(ask = TRUE)

add_packages(packages = NULL, python_ver = "auto", ...)

ensure_rpymat(verbose = TRUE, cache = TRUE)

matlab_engine()

call_matlab(
  fun,
  ...,
  .options = getOption("rpymat.matlab_opt", "-nodesktop -nojvm"),
  .debug = getOption("rpymat.debug", FALSE)
)

```

Arguments

env_name	alternative environment name to use; default is "rpymat-conda-env"
...	for add_packages, these are additional parameters passing to conda_install ; for call_matlab, ... are the parameters passing to fun
matlab	'Matlab' path to add to the configuration path; see 'Details'
python_ver	python version to use; see 'Configuration'
packages	additional python or conda packages to install
update	whether to update conda; default is false
force	whether to force install the 'Miniconda' even a previous version exists; default is false. Setting false=TRUE rarely works. Please see 'Configuration'.
ask	whether to ask for user's agreement to remove the repository. This parameter should be true if your functions depend on remove_conda (see 'CRAN Repository Policy'). This argument might be removed and force to be interactive in the future.
verbose	whether to print messages
cache	whether to use cached configurations; default is true
fun	'Matlab' function name, character (experimental)
.options	'Matlab' compiler options
.debug	whether to enable debug mode

Value

None

Background & Objectives

Package `reticulate` provides sophisticated tool-sets that allow us to call python functions within R. However, the installation of 'Miniconda' and python can be tricky on many platforms, for example, the 'M1' chip, or some other 'ARM' machines. The package `rpymat` provides easier approach to configure on these machines with totally isolated environments. Any modifications to this environment will not affect your other set ups.

Since 2014, 'Matlab' has introduced its official compiler for python. The package `rpymat` provides a simple approach to link the compiler, provided that you have proper versions of 'Matlab' installed. [Here](#) is a list of 'Matlab' versions with official compilers and their corresponding python versions.

Configuration

If 'Matlab' compiler is not to be installed, In most of the cases, function `configure_conda` with default arguments automatically downloads the latest 'Miniconda' and configures the latest python. If any other versions of 'Miniconda' is ought to be installed, please set options "`reticulate.miniconda.url`" to change the source location.

If 'Matlab' is to be installed, please specify the 'Matlab' path when running `configure_conda`. If the environment has been setup, `configure_matlab` can link the 'Matlab' compilers without removing the existing environment. For 'ARM' users, unfortunately, there will be no 'Matlab' support as the compilers are written for the 'Intel' chips.

Initialization

Once conda and python environment has been installed, make sure you run `ensure_rpymat()` before running any python code. This function will make sure correct compiler is linked to your current R session.

Examples

```
# The script will interactively install \code{conda} to `R_user_dir`  
## Not run:  
  
# Install conda and python 3.9  
  
configure_conda(python_ver = '3.9')  
  
# Add packages h5py, pandas, jupyter  
  
add_packages(c('h5py', 'pandas', 'jupyter'))  
  
# Add pip packages  
  
add_packages("itk", pip = TRUE)  
  
# Initialize the isolated environment  
  
ensure_rpymat()
```

```
# Remove the environment  
remove_conda()  
  
## End(Not run)
```

jupyter

Install, register, launch 'Jupyter' notebook to the virtual environment

Description

Install, register, launch 'Jupyter' notebook to the virtual environment

Usage

```
add_jupyter(..., register_R = TRUE)  
  
jupyter_bin()  
  
jupyter_register_R(  
  user = NULL,  
  name = "ir",  
  displayname = "R",  
  rprofile = NULL,  
  prefix = NULL,  
  sys_prefix = NULL,  
  verbose = getOption("verbose")  
)  
  
jupyter_options(  
  root_dir,  
  host = "127.0.0.1",  
  port = 8888,  
  open_browser = FALSE,  
  token = rand_string()  
)  
  
jupyter_launch(  
  host = "127.0.0.1",  
  port = 8888,  
  open_browser = TRUE,  
  workdir = getwd(),  
  async = FALSE,  
  ...,  
  dry_run = FALSE
```

```

)

jupyter_check_launch(
    port = 8888,
    host = "127.0.0.1",
    open_browser = TRUE,
    workdir = getwd(),
    async = "auto",
    ...
)

jupyter_server_list()

jupyter_server_stop(port, ...)

jupyter_server_stop_all(...)

```

Arguments

...	for <code>add_jupyter</code> , these are additional parameters passed to <code>jupyter_register_R</code> ; for <code>jupyter_launch</code> , these are additional parameters passed to <code>jupyter_options</code>
<code>register_R</code>	whether to register IRkernel to the notebook
<code>user, name, displayname, rprofile, prefix, sys_prefix, verbose</code>	see installspec
<code>root_dir, workdir</code>	default root directory of the notebook
<code>host, port</code>	'IP' and port of the hosting 'URL'
<code>open_browser</code>	whether to open the browser once launched
<code>token</code>	access token of the notebook
<code>async</code>	whether to open the notebook in the background
<code>dry_run</code>	whether to display the command instead of executing them; used to debug the code

Value

`jupyter_bin` returns the 'Jupyter' notebook binary path; `jupyter_options` returns the 'Jupyter' configuration in strings; `jupyter_server_list` returns a table of existing local 'Jupyter' server hosts, ports, and tokens; `jupyter_check_launch` returns true if a new server has been created, or false if there has been an existing server at the port; other functions return nothing.

Examples

```

## Not run:

# Requires installation of conda
library(rpymat)

```

```
# Install conda, if you have done so, skip
configure_conda()

# Install Jupyter notebook
add_jupyter(register_R = TRUE)

# Utility functions
jupyter_bin()

# Please install `dipsaus` package to enable `async=TRUE` with
# better experience
jupyter_launch(async = FALSE, open_browser = TRUE)

## End(Not run)
```

repl_python

Enable interactive 'python' from R

Description

Allows users to type 'python' command from R console for quick code evaluation or debugging.

Usage

```
repl_python(...)
```

Arguments

... passed to [repl_python](#) in 'reticulate' package

Value

See [repl_python](#)

reticulate-reexports *Wrappers around 'reticulate' package*

Description

Almost the same with 'reticulate' functions, with rpymat enabled by default and some minor changes (see parameter convert and local)

Usage

```
tuple(..., convert = FALSE)

py_help(object)

np_array(data, ...)

import(module, as = NULL, convert = FALSE, delay_load = FALSE)

r_to_py(x, convert = FALSE)

py_to_r(x)

py_to_r_wrapper(x)

py_str(object, ...)

py_run_string(code, local = TRUE, convert = FALSE)

py_bool(x)

py_dict(keys, values, convert = FALSE)

py_call(x, ...)

py_del_attr(x, name)

py_del_item(x, name)

py_eval(code, convert = FALSE)

py_get_attr(x, name, silent = FALSE)

py_set_attr(x, name, value)

py_get_item(x, key, silent = FALSE)

py_set_item(x, name, value)
```

```
py_len(x, default = NULL)
```

```
py_none()
```

Arguments

convert	whether to convert 'Python' objects to R; default is FALSE. This is different to 'reticulate', but less error prone: users must explicitly convert 'Python' objects to R.
object, data, x, code, keys, values, ...	passed to corresponding 'reticulate' functions as data inputs
module, as, delay_load	import 'Python' module as alias
local	whether to execute code locally so the memory sets free when the function ends; default is true
name, silent, key, value, default	other parameters passing to the 'reticulate' functions

Value

'Python' built-in objects

Examples

```
library(rpymat)
if(interactive() && dir.exists(env_path())) {

  # tuple
  x <- tuple(1, 2, "a")
  print(x)

  # convert to R object
  py_to_r(x)

  # convert R object to python
  y <- r_to_py(list(a = 1, b = "s"))

  # get element
  py_get_item(y, "a")

  # get missing element
  py_get_item(y, "c", silent = TRUE)

}
```

run_command	<i>Execute command with additional environments</i>
-------------	---

Description

Enables 'conda' environment

Usage

```
cmd_create(command, shell, use_glue = TRUE)

cmd_set_env(command, key, value, quote = TRUE, quote_type = "cmd")

cmd_set_workdir(command, workdir)

cmd_set_conda(command, conda_path, env_path)

cmd_build(command, .env = parent.frame(), ...)

detect_shell(suggest = NULL)

run_command(
  command,
  shell = detect_shell(),
  use_glue = FALSE,
  enable_conda = TRUE,
  stdout = "",
  stderr = "",
  stdin = "",
  input = NULL,
  env_list = list(),
  wait = TRUE,
  timeout = 0,
  ...,
  workdir = getwd(),
  dry_run = FALSE,
  print_cmd = dry_run,
  glue_env = parent.frame()
)
```

Arguments

command	system command
shell	shell type
use_glue	whether to glue the command; default is false
key, value	environment variable key and value

quote, quote_type	whether to quote the environment variables and what quote type should use; see shQuote
workdir	the working directory
conda_path	'conda' path; default is conda_path
env_path	'conda' environment path; default is env_path
suggest	suggested shell type; default is 'cmd' on windows, or 'bash' on others
enable_conda	whether to activate 'conda'
stdout, stderr, stdin, input, wait, timeout, ...	passed to system2
env_list	a key-value pairs of environment variables
dry_run	whether to dry-run the command (do not execute, simply returns the command), useful to debug
print_cmd	whether to print the command out
glue_env, .env	the environment to evaluate variables when use_glue is true

Value

All the functions return a list with class `rpymat_system_command` except for `run_command`, which returns the exit code by [system2](#).

Examples

```
run_command("conda install -y numpy", dry_run = TRUE)

a <- "This is a message"
run_command('echo "{a}"', dry_run = TRUE,
            enable_conda = FALSE, use_glue = TRUE)

## Not run:

# Use `jupyter_launch()` instead. This is just a demonstration
run_command('{jupyter_bin()} server list', use_glue = TRUE)

## End(Not run)
```

run_script	<i>Run 'Python' script</i>
------------	----------------------------

Description

A wrapper of [py_run_file](#), but with rpymat enabled

Usage

```
run_script(x, work_dir = NULL, local = FALSE, convert = FALSE)
```

Arguments

x	script path
work_dir	working directory of the script
local, convert	passed to py_run_file

Value

The values returned by [py_run_file](#)

Examples

```
## Not run:  
  
# Please configure conda environment first  
  
x <- tempfile()  
writeLines(c(  
  "import re",  
  "zipcode = re.findall(r'[0-9]{5,6}', r.address)"  
) , con = x)  
  
address <- '2341 Main St., 72381'  
rpymat::run_script(x)  
  
py$zipcode  
  
## End(Not run)
```
